JAMUN GROWERS OVER THE MOON

Virtues of the violet fruit reach Old Blighty as state exports first consignment to London

Helps control blood sugar without being the bitter pill

PAVAN KUMAR K
HUSBALLI DHNS

Only frozen jamun or its seed powder used to be exported all these years. Exporting fresh fruit is expected to open new avenues for farmers. Its low shelf life remains a challenge, but employing better processing technology can help overcome it. DH PHOTO

A consignment of nearly 250 kg of the state's jamun variety (nerale hannu in Kannada) was shipped to London recently.

This is the first time such a huge quantity of raw jamun, said to have very high medicinal qualities but low shelf life, is being airlifted from India.

Union Minister of Commerce & Industry Piyush Goyal recently shared the news on 'X' of the fruit's export to London.

The first consignment was procured from a Farmer Producer Organisation (FPO) in Nelamangala and was shipped from Bengaluru on June 19. It reached London on June 23.

If there is positive feedback, the state's farmers are expected to export another tonne to London next week.

The state's arid districts, including Kolar, Chikkaballapur, Tumakuru, Ballari and Koppal, are among the highest growers of jamun.

The fruit is in very high demand not just in the domestic market, but also abroad for its medicinal qualities. Doctors say it helps regulate blood sugar levels.

Until now the Agricultural and Processed Food Products Export Development Authority (APEDA) used to export only frozen jamun or its seed powder to foreign markets. Exporting fresh fruit will now open new avenues for farmers.

Maresh K N, a farmer from Kannamangala in Shidlaghatta taluk of Chikkaballapur district, says the domestic market for jamun is very volatile.

"I have sold a kg of jamun for Rs 300 and also Rs 10. There have been instances when I have not harvested the fruits on my 2.5 acres of land as labour and transport costs are much higher than returns."

"Exporting the fruit might help market prices to stabilise," he says.

One of the biggest challenges for both growers and traders is the fruit's fragile nature.

Traders say transporting the fruit even to the domestic market is difficult as it starts to break and rot. Jamun is harvested for nearly one-and-a-half months between May and June. Excess rain can adversely affect the fruit's longevity as it can be affected by fungus and pests.

Processing technology

Food entrepreneur Parthasarthi Nara says India can increase the export of jamun across the globe if it starts packaging and preserving the fruit properly.

Nara says processing technology can help farmers export medicinal and high-value fruits.

U Dharma Rao, general manager of APEDA who was instrumental in the first export of jamun, says they are hopeful of getting positive response from London.

"We are also looking at USA, Europe and Middle East as the next big markets".

He rejected the argument that export of jamun would increase prices locally as the quantity being shipped is minuscule compared to domestic consumption.

Sowing the seeds for a space experiment

Girish Pattanashetti
HUBBALLI

As Indian astronaut Shubhanshu Shukla's Axiom-4 mission (Ax-4) to the International Space Station (ISS) was launched successfully on Wednesday, the University of Agricultural Sciences (UAS) has something to cheer about. Along with Mr. Shubhanshu, the seeds sent by the university will also be reaching the ISS.

In an experiment that is of relevance to the crew's nutrition, principal investigator from UAS, Dharwad, Ravikumar Hosamani, and co-investigator Sudheer Siddapureddy from IIT-Dharwad have taken up the project under which two types of seeds – green gram and fenugreek (methi) – have reached the ISS for an experiment.

Prof. Hosamani, an assistant professor of biotechnology in UAS-D, and Prof. Siddapureddy, associate professor from IIT-Dharwad, were in the United States of America between June 2 and 11.

Chosen ones: Green gram and fenugreek from Dharwad have been sent to the International Space Station, awesome echoes

"We personally handed over the seeds in dry form to the integration team at the Kennedy Space Centre-NASA," Prof. Hosamani told *The Hindu*.

Sprouting in space

In the experiment, Mr. Shukla will add water to these seeds, which are likely to begin sprouting within two to four days. The sprouts will then be frozen on the space station until they return to earth. Upon their return, officials would assess the sprouting rate (germination) of seeds, evaluate their nutritional quality, analyse changes in phytohormone dynamics, and study the sprout transcriptome response to space conditions. This apart, they plan to investigate microbial growth in the space sprout, Prof. Hosamani said.

This research is aimed at contributing towards the development of India-centric salad vegetables for astronaut nourishment in space as a plant-based food production system is crucial for supporting long-term human space exploration.

"While salad crops like lettuce, tomato, radish, cabbage, carrot, and onion are considered ideal for supplementing the crew's diet in space, the cultivation of mature plants in space required complex controlled environments. In contrast, sprouting salad seeds in space can be achieved with a simple container and a manual water injection system, without the need for light and other electronics," he said.

The investigators believe that considering the high cost involved in sending food to the ISS, growing two fresh vegetables on-board spacecraft or on extraplanetary surfaces could be an ideal solution for supplementing crew diets.

Research aims to contribute towards the development of India-centric vegetables for astronaut nourishment
